

SPIDER

Jumping Spider CARE GUIDE

- Bond with your spider companion to build comfort.
- If your spider appears nervous or jumpy, create a cozy space by cupping your hands. Exercise patience until they relax, moving gently to avoid sudden movements.
- Maintain a quiet environment to prevent startling your spider with loud noises.
- If your spider gets stuck in tight spots, use a soft brush to assist in maneuvering.

Use tweezers for placing appropriately sized soft-bodied creatures like wingless fruit flies (for babies), mealworms, wax worms, small roaches, or crickets. This promotes natural hunting and enhances pet well-being. Avoid house flies due to potential pesticide exposure.

Refrain from disturbing spiders during meals.

FEEDING FREQUENCY Babies: weekly

Sub-adults: every 3-8 days Adults: every 5-10 days

WATERING

Spiders have "book lungs" outside their bodies, so avoid bowls to prevent drowning. Moist the enclosure's side daily or wet the tip of a q-tip for them to drink if needed.

I'm STARVING!

Ready for my next meal!

Nice and full from my meal!

WAY TOO FULL. Wait to feed me!

Remove dead bugs, molts, and clean up poop for a tidy environment. Note: Webbing doesn't require any cleaning.

Spiders usually molt inside their web or hammock. It's important not to disturb them during this time. Remember, it's okay if they aren't eating! Molting might take longer as spiders get older. Do not offer food when they are molting but continue to mist daily for needed humidity.

Life Expectancy

Regal jumping spiders tupically live for about 18-24 months, with female spiders often having a longer lifespan than male spiders.

Temperature

Maintain a comfortable temperature between 67 to 85 degrees Fahrenheit for these spiders. Spritz daily to maintain humidity levels.

If your spider's abdomen is unusually large, she might be pregnant (gravid). Expect her to lay an egg sac in her webbing or hammock, usually within a few days. She'll guard the eggs until they hatch.

- Provide harmless food like wax worms during this period.
- Adult females, whether mated or not, can lay egg sacs. Infertile ones will be runny.
- You can take out or leave the egg sac; the eggs will hatch into tiny spiders when ready.

- Each spider is unique, and has their own special personality, much like people.
- Light stimulates spiders to go out and Facts hunt. They sleep at night, like humans!
- Male spiders are black with white spots, while females come in brown, gray, or orange. Outside of spending time with you or eating, spiders
- are typically solitary creatures.
- If a spider accidentally loses a leg, no worries! It'll grow back during molting.

If your spider feels threatened, watch for warning signs: front arms up and chelicerae (fangs) come out. Be patient and calm, let them settle down. Spiders are usually very, very friendly unless they feel their life is in danger.
